

## Regarding Postman requests:

### **Explanation of Missing IDs in Postman Requests**

During testing with Postman, some API requests encountered errors related to missing IDs for customers, customer addresses, or products. This issue occurs because earlier delete requests remove these entities from the database. Subsequent requests that depend on the deleted IDs fail due to the lack of a corresponding record in the database.

For instance, creating a new **CustomerAddress** requires a valid **Customer ID**. If the customer associated with that ID has already been deleted in a previous test, the database rejects the operation due to a foreign key constraint violation.

This behavior is expected as the database reflects the state resulting from sequential API requests. These scenarios were not adjusted for Postman tests because they align with typical application behavior when entities are deleted. Testing these endpoints independently resolves the issue, ensuring that all necessary dependencies are present in the database.
